

1. Provide another example (i.e., *not* the pizza deal scenario presented by Guest & Martin 2020) where an informal, intuitive theory would incorrectly predict something that a quantitative/computational theory would accurately predict.
2. Van Rooij and Baggio 2020 claimed that all theories in psychology (and I proposed in neuroscience as well) are descriptions of capacities. How does the definition of the capacity determine the form of the theory used to describe it (hint: think Marr's levels of analyses)?
